Design Task — Create an AI Agent

Role: UI Designer
Time: 4–6 hours (take-home assignment)
Deliverable: Figma (or similar) link + 5-minute walkthrough

1. Context

Our platform allows teams to build AI agents that interact with customers across different channels.

An agent can support:

- **Voice** — phone calls
- **Email** — email conversations
- **Chat** — coming soon

Currently, when a team member selects **Create → Agent**, they land on a single page where they enter the initial details and choose the channels their agent will support.

2. Part 1 — Create Agent Page

Design the **Create Agent** page that users see after selecting *Create → Agent*.

The attached file, `Create Agent - fields per channel.csv`, contains the fields, default values, options, and rules that need to be included.

It covers the following sections:

- Creation
- Prompt
- Tools
- Model Settings
- Voice Settings
- Email Settings
- Try It
- Publish

The CSV tells you what needs to be included, but not how the page should look or work. You can decide the layout, grouping, order, labels, and controls. For example, you might use toggles, dropdowns, or segmented controls depending on what makes the most sense.

Make sure every required field and rule from the CSV is covered.

States to design

Please include the following states in your design:

1. Default state

- Voice is selected by default.
- Cascaded is the selected model.
- Show the relevant fields for this setup.

2. Realtime Voice

- Voice is enabled.
- Realtime Voice is selected.
- Show the expanded view with its relevant settings.

3. Email only

- Voice is switched off.
- Email is the only selected channel.
- Show how the page changes based on this selection.

4. Error states

- The user tries to create an agent without entering a name.
- The user tries to create an agent without selecting a channel.

Show how these errors appear and how the user can fix them.

5. Chat unavailable

- Show how Chat looks while it is unavailable.
- Make it clear that users cannot select it yet.

3. Part 2 — Agent Configuration

After creating an agent, users need to configure its settings. Design this view and show how users move between the different sections. Fields are available in the same csv file.

Include navigation for:

- Prompt
- Tools
- Model Settings
- Voice Settings
- Email Settings

Also show where users can access **Try It** and **Publish**.

You don't need to design every section in detail. Focus on a clear overall structure and choose one of the following for a full-detail screen:

- Voice Settings
- Email Settings

Show how the settings and controls are organised within your chosen section.

4. Nice to Have

These are optional, but feel free to include them if time permits.

- **Responsive layout:** Show how the design adapts to a narrower screen of around 900px.
- **After Create:** Add a short note explaining where the user lands after creating an agent and what happens next.

5. Design Guidelines

- Use a light theme.
- Use Lato as the typeface.
- Stick to one accent colour.
- Keep body text at 14px or above.
- Include clear focus states for interactive elements.
- Make disabled controls look clearly different from active ones.

Keep the interface clean and easy to follow. This is a tool people will use for work, so prioritise clarity over decoration.

6. What to Submit

Please share:

- A Figma link with your designs.
- All the required states listed above.
- The overall agent configuration view.

- One detailed screen for either Voice Settings or Email Settings.

7. What We'll Look At

Hierarchy: Is channel selection easy to find and understand?

States: Have you considered defaults, errors, disabled controls, and expanded or collapsed sections?

Consistency: Are spacing, alignment, and components consistent across the screens?

Copy: Are labels and helper text clear and easy to understand?

Reasoning: Can you explain your design decisions and the trade-offs you made?

We're interested in how you approach the problem, not just how polished the final screens look.

8. What You Don't Need to Do

- Spend time on branding, illustrations, or logos.
- Design every settings section in full detail.
- Build the actual product or implement the screens in code.

One detailed settings screen is enough, as long as the overall configuration structure is clear.
